#### Results

This study was carried out upon 90 mother – infant pairs who were classified into two main groups. The first group (group 1) including 30 LBW infants who were cared for by KMC maneuver. Their birth weight ranged from 1500 to 2050 grams with a mean birth weight of 1790 grams ( $\pm$  156). They included 11 males and 19 females. The second group (group 11) included 60 LBW infants cared for by the traditional incubator care. This group was subdivided according to type of feeding into two subgroups. The first subgroup (group 11a) included 30 LBW been fed infants who had by maternal breastfeeding predominantly. Their birth weight ranged from 1500 to 2220 grams with a mean birth weight of 1736 grams (± 204). They included 16 males and 14 females. The second subgroup (group 11b) included 30 LBW infants who had been fed by artificial feeding. Their birth weight ranged from 1500 to 2200 grams with a mean birth weight of 1740 grams (± 190). They included 14 males and 16 females. The mothers of all cases (90) were subjected to assessment for depressive symptoms by using the Beck Depression Inventory at 6 weeks postpartum (Abd El-**Fattah**; 1996). We assessed the knowledge, attitude and practice (KAP study) of (57) physicians and nurses towards KMC in NICUs of the targeted hospitals included in the study before and after the implementation of KMC maneuver by using a previously prepared questionnaire.

# Our results will be shown in the following tables and figures:

| (21.97±6.74) | Sig.         | NS           |  |  |

LSD at 0.05 = 4.27

The table shows the LSD of maternal depression scores among all studied groups with no significant statistical difference between group 1 and group 11a, and between group 11a and group 11b. Only the significant statistical difference was present when group 1 (mean of maternal depression scores = 17.70) was compared with group 11b (mean of maternal depression scores = 20.03).

**Table (11):** 

Correlation of maternal depression scores with other variables included in the study in all studied groups.

| Variables                    | r      | P     |  |
|------------------------------|--------|-------|--|
| Birth weight                 | -0.292 | 0.005 |  |
| Gestational age              | -0.211 | 0.046 |  |
| Maternal age                 | 0.267  | 0.011 |  |
| Father age                   | 0.280  | 0.008 |  |
| Father-mother age difference | 0.186  | 0.080 |  |
| Length of hospital stay      | 0.277  | 0.008 |  |
| Age of end point             | 0.243  | 0.034 |  |
| Morbidity age                | 0.345  | 0.069 |  |
| Mortality age                | -0.119 | 0.699 |  |

<sup>\*</sup>P > 0.05: non-significant

The table shows that there is significant +ve correlation between maternal depression scores and father age, mother age, length of hospital stay and age of end point (P<0.05) in all studied groups. Also, there is a significant –ve correlation between maternal depression scores and birth weight, gestational age (P<0.05) in all studied groups included in the study. Otherwise, there is no significant correlation between maternal depression scores and other parameters included in the study in all groups.

<sup>\*</sup>P < 0.05: significant

<sup>\*</sup>P< 0.001: highly significant
