RESULTS

1 – Isolation of bacterial isolate

In this experiment 50 bacterial isolates were collected from hospitals of Zagazig University. Samples were collected from operating rooms and nursery incubators. Also samples were taken from operating tablets, floor, instruments, beds, windows, doors, lamps and nursery incubator using sterile swaps on nutrients agar as shown in materials and methods . The total bacterial isolates, source and their origin are tabulated in Table (3) .

2 – Identification of bacterial isolates

Different morphological , physiological and biochemical tests were tabulated in Table (4) . It is clear that the dominant bacterial isolates were *E.coli, Pseudomonas* spp*, Klebsiella, Proteus* spp and *S.aureus* . All the experimental bacterial isolates were non spore forming. All the isolates cells are rods and Grams negative, except *S. aureus* where its cells were clusters of cocci and Grams positive. All bacterial isolates showed positive results with catalase test. *Pseudomonas* spp showed positive results with oxidase test.

All bacterial isolates gave negative result with coagulase test except *S. aureus*. With respect to indole test *E. coil* and *Proteus* spp gave positive results. All bacterial isolates gave positive results with urease test except *E. coil*. with respect to citrate test *Klebsiella* spp, *Pseudomonas* and *Proteus* spp gave positive results while *E. coil* and *S. aureus* gave negative results . All bacterial isolates gave negative results with methyl red test. All bacterial isolates gave positive results with nitrate reduction test while *Pseudomonas* spp dose not. *E. coil, S. aureus* and *Klebsiella* spp could

ferment lactose with acid and gas production while *Pseudomonas* spp and *Proteus* spp were not.

3 - Effect antibiotics on bacterial isolates growth

In this experiment, the effect of antibiotics was tested on all the bacterial isolates as illustrated in Tables (5, 6). Impinem showed high effect for both Gram negative and Grams positive bacteria except *E.coli* no (47) which showed intermediate result, choloramephnicol showed 38 resistant and 2 sensitive in case of Gram negative bacteria while gave resistant and 4 sensitive in case of Gram positive. Gentamicin antibiotics show 15 sensitive, 12 intermediates and 13 resistant in Gram negative isolates .

Clindamycin antibiotics had no effect of Gram negative bacteria, ciprofloxacin show high sensitivity for Gram negative bacteria, it was tested on 40 samples of Gram negative bacteria, it showed 35 sensitive and 4 intermediate and 1 resistant. Piperacillin had low sensitive for Gram negative bacteria, it showed 35 resistant, 5 intermediate and 0 sensitive .

Erythomycin had tested for 10 samples Grams positive bacteria show 4 sensitive and 6 resistant. Ofloxacin showed high sensitivity for all Gram positive samples while ampicillin and sulphamethoxazole have not any effect for Gram positive bacteria.

3.1Suceptibility of Gram negative and Gram positive bacterial isolates to antibiotic

Impinem and ciprofloxacin antibiotics show high sensitive to different Gram positive bacterial isolates with percentage 97.5, 87.5 respectively while gentamicin show moderate sensitive to same isolates with percentage 32.5 % . Piperacillin , clindamycin and chloramephnicol have few or no effect on Gram negative isolates with percentage 2.5 . 0.5 % respectively .

Impinem and ofloxacin antibiotics show high sensitive to different Gram positive bacterial isolates with percentage 100 % for both. chloramephnicol show moderate sensitive to same isolates with percentage 60 % . Ampicillin, sulphamethoxazole and erythromycin have weak effect on Gram positive isolates .

Table (7) : Susceptibility of Gram negative bacterial isolates to Antibiotics

Antibiotics / Activity	Impinem	Chloramephnicol	Gentamicin	Clindamycin	Ciprofloxacin	Piperacillin
Resistant %	0	95	37.5	100	2.5	87.5
Moderately %	2.5	0	30	0	10	10
Sensitive %	97.5	5	32.5	0	87.5	2.5

3.2. Determination of MIC and MBC for different bacterial isolates

In this experiment, the minimum inhibitory concentrations (MIC) and minimum bactericidal concentrations (MBC) of impinem and ciprofloxacin were determined for *E.coli* , *Pseudomonas* spp and *Proteus* spp. The obtained results in Tables (9,10), clearly illustrate that the impinem was active than ciprofloxacin against different *E.coli* isolates hence it gave lowest values of MIC and MBC than ciprofloxacin, MIC gave values (20-30 ug/ml) for ciprofloxacin but gave values (10-20 ug/ml) for impinem against *E.coli* isolates.

It is clear also that impinem was active against *Pseudomonas* spp than ciprofloxacin hence it gave lowest values than ciprofloxacin MIC gave values. The results showed that MIC values for *Pseudomonas* spp no 21,23,42 and 43 were 20,30,30 and 30 ug/ml respectively in case of ciprofloxacin and the same isolates gave MBC values 20,30,20 and 20 ug/ml in case of impinem used.

The same action of both impinem and ciprofloxacin occurs against *Proteus* spp isolates MIC values for *Proteus* spp was (30 ug/ml) for ciprofloxacin and (20 ug/ml) for impinem . Generally from this results it is obvious that MIC values for impinem less than ciprofloxacin so impinem become more effective than ciprofloxacin for *E.coli , Proteus* spp and *Pseudomonas* spp .

Table(9) MIC and MBC (ug/ml) of ciprofloxacin against selected clinical bacterial isolates

4 - Effect of different essential oils on the bacteria isolates : -

In this experiment, the effect of ten (thyme, caraway, clove, garlic ,lemon, peppermint, jasmine, anise, rosemary and chamomile) **,** essential oils were studied on both Gram negative and Gram positive bacteria , the obtained results are tabulated in tables (11,12). It is obvious from the results that thyme and rosemary inhibit the growth of Gram negative bacteria, caraway oil have no effect on *Pseudomonas* spp and have weak effect on another Grams negative bacteria where chamomile have not any effect on Gram negative of bacterial isolates. Thyme, cloves, pepper, rosemary and chamomile inhibit growth of *S.aureus* while caraway, lemon , jasmine and anise have low effect on *S.aureus* while garlic had no effect on *S.aureus.*

Table (11) : Effect of different oils on the growth of Gram negative bacterial isolates

5 - Combination between antibiotics and essential oils

The effect of combination between most effective antibiotics and most active essential oil against Gram positive and Gram negative bacterial isolates were evaluated to study the synergetic or antagonistic effect of combination between antibiotics as impinem and ciprofloxacin and essential oils as thyme and rosemary compared with effective of antibiotics and oils alone . The obtained results in Table (13), photo (9) and figures (5,6), clearly illustrated that the combination between impinem and ciprofloxacin with both thyme and rosemary gave highly synergetic effect against Gram negative bacterial isolates especially *E.coli* no (13) and (49) . Also combination between impinem and ofloxacin with chamomile and clove gave highly effect against Gram positive bacterial isolates especially *S.aureus* no (44) .

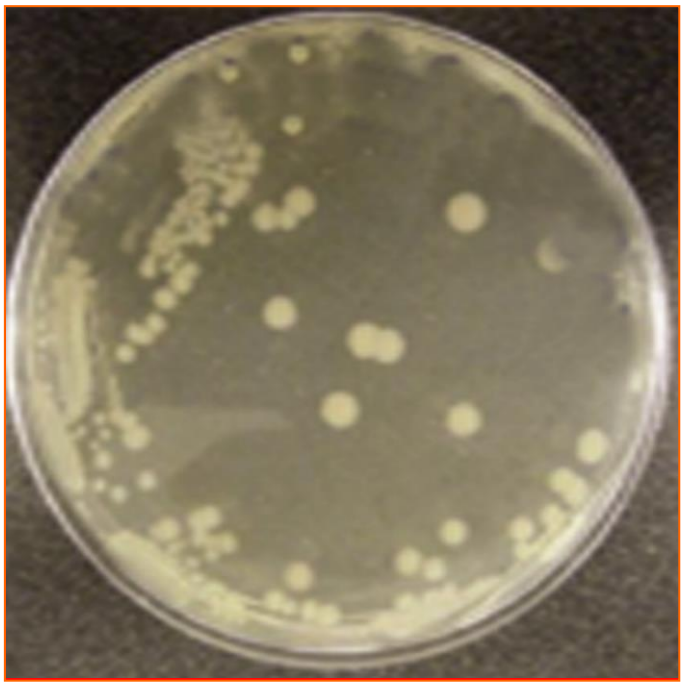
6.1. Antibacterial activity of ultraviolet rays

In this experiment, the effect of ultraviolet rays (254 nm) was studied on the survival of bacterial isolates of viable cells after exposure for different periods (0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 ,11 ,12 minutes) at 20 cm distance from UV lamp . The obtained results are demonstrated in Table (14) , photo (10) and figures (7,8) which showed that the elapsing of the exposure time to short wavelength ultraviolet (254 nm) at the distance of 20 cm caused a decrease in the percentage of survival of cells .This decrease with increasing the exposure time and the total viable counts for *E.coli* no (11) and (12) complete inhibited after (11) minutes of exposure to UV . *Proteus* spp complete inhibited after 9 minutes, *Pseudomonaus* spp no (21), (42) after 11 minutes and *E.coli* no (49) after 10 minutes, This means that the majority of cells failed to survive after the first 8 minutes of exposure.

E.coli **after 2 minutes of UV rays**



E.coli **after 7 minutes of UV rays**

6.2. Antibacterial activity of gamma irradiation

The result of survival of the subjected viable cells are shown in table (15) and figures (9) and (10). these results showed that increasing of gamma radiation doses decreased that total number of viable bacterial cells and the total viable counts for *E.coli* no (11), (12) ,(13) and (49) were completely inhibited after 3 KGy , *Proteus* spp complete inhibited at 4 KGy, *Pseudomonas* spp no (21) , (42) and (43) completely inhibited at 5 KGy. It was found that the gamma irradiation doses decreased the percentages of the total number of viable bacterial cells.

Table (15) : Effect of gamma irradiation doses on some bacterial isolates

Bacterial Isolates	Dose (KGy)	No.of Cells	log no	Bacterial Isolates	Dose (KGy)	No. of cells	no log

6.3. Antibacterial activity of X radiation :

In this experiment, the effect of X radiation after exposure of different doses (0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 3.5,4, 4.5 and 5 kgy) for bacterial isolated, the results were shown in Table (16) and Figures (11) and (12). These results showed that the total viable counts for *E.coli* no (11), (12),(13) completely inhibited after 3 KGy of X rays. *Proteus* spp and *Pseudomonas* spp no (21), (42) were complete inhibited after 4 KGy of X rays while *Pseudomonas* spp no (43) was complete inhibited after 4.5 KGy of X ray. This means that the X radiation doses decreased the percentages of the total number of viable bacterial cells.

Table (16) : Effect of X rays on the growth of some bacterial isolates

Bacterial Isolates	Dose (KGy)	No of cells	Log . no	Bacterial isolates	Dose (KGy)	No of cells	no log

7 - Effect of essential oils on the ultrastrcture of *Pseudomonas* spp using Transmission Electron Microscope (TEM)

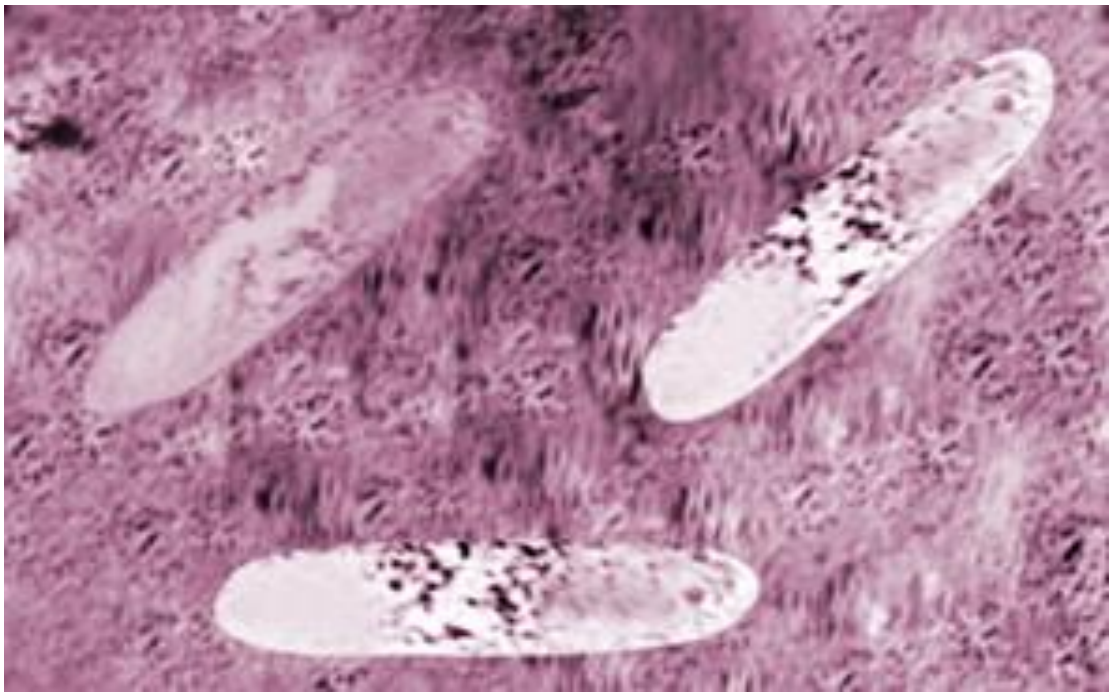
7.1. Effect of thyme oil

The thyme oil was the most effective against clinical *Pseudomonas* spp no (20) , and this oil was selected to study their effect on ultrastrcture of *Pseudomonas* spp to explain the sensitivity of this isolates to thyme oil and compared with non treated isolates .

The figures (16,17) clearly demonstrated that ultrastrcture of *Pseudomans* spp no (20) by Transmission Electron Microscope (TEM) after exposed to *Thymus vulgaris* (Thyme) oil had destructive effect on cell wall and cytoplasm substance compared with non treated (control) *Pseudomonas* spp .

Control (without oil)

Figure (13) :Transmission electron micrographs of *Pseudomonas* spp

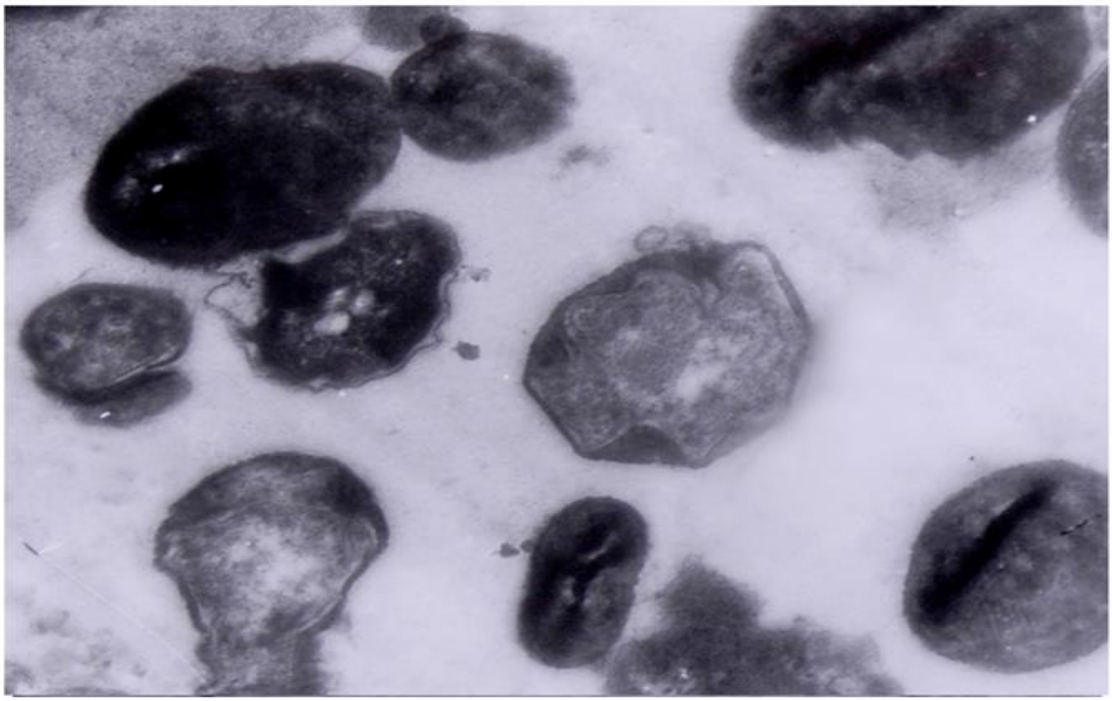


Treated(with oil)

Figure (14) : Transmission electron micrographs of *Pseudomonas* spp sensitive to *Thymus Vulgaris L* (Thyme) essential oil .

7.2. Effect of Jasmine oil

From antibacterial activity of different essential oils , it was found that *Jasmium gradiflorum L.*(Jasmine) essential oil had no effect on *Pseudomonas* spp, its effect was tested on the ultrastrcture of *Pseudomonas* spp no (24) using Transmission electron Microscope (TEM). These micrographs were illustrated in Figures (18 and 19). The micrograph of control (without essential oil) and treated (with essential oil) showed no obvious effect .



Control (without oil)
