**Chapter (III)**  
**The Spectral and Voltammetric Characterization**  
**of The Organic Ligands**

### **3.1. The electronic absorption spectra of azo dye and Schiff base compounds in different organic solvents**

The electronic absorption spectra of azo dye and Schiff base compounds derived from 6-amino-2,3-dihydroxyquinoxaline were studied in six organic solvents, the solvents included ethanol, acetonitrile, DMF, 1,4-dioxane, n-hexane and acetone. The changes in extinction and displacements of absorption bands can take place according to the nature of solvent used. This displacement includes either red or blue shifts on going from nonpolar to polar solvent. These effects are due to the following reasons:

- 1- The physical properties of the organic solvent such as dipole moment, dielectric constant, refractive index and its ability to interact through hydrogen bonding with the solute molecules.
- 2- The difference in solvation energy from one solvent to another and also on going from the ground to the excited state during excitation in the same solvent.
- 3- The changes in polarities and dipole moments of the solute on excitation.

The studies reveal that the electronic absorption spectra involve bands due to electronic transitions within the various moieties **locally excited (LE)** attached either to the azo group or to the azomethine group leading to absorption in the UV region and band corresponding to the electronic excitation of the  $\pi$  and n-electrons on the (-N=N-) and (-CH=N-) systems which can be activated by **charge transfer (CT)** interactions. The spectra of the ligands under investigation can be classified into two regions. The first one below  $\approx 310$  nm being attributed to the localized transitions of substituted aromatic rings. The second region is located above  $\approx 310$  nm and can be assigned to

transitions within the (-N=N-) or (-CH=N-) systems, which are influenced by the different types of intermolecular charge transfer liable to occur within the molecules.

### ***3.1.1. The electronic absorption spectra of azo dyes in ethanol***

The electronic absorption spectra of azo dye ligands ( $I_{a-c}$ ) in ethanol are shown in Fig. (2). The electronic spectra of the azo compounds under investigation show mainly three absorption bands within absorption region 190-500 nm. The first band at 263 and 269 nm for ligands  $I_a$  and  $I_b$  which has  $\epsilon_{\max}$   $0.90 \times 10^4$  and  $0.24 \times 10^4$  L mol<sup>-1</sup> cm<sup>-1</sup> respectively. This band is due to moderate energy transition ( ${}^1B_a \leftarrow {}^1A$ ) state in the naphthyl moieties for ligands  $I_a$  and  $I_b$ . The second band has  $\lambda_{\max}$  at wavelength 284, 273 and 242 nm and  $\epsilon_{\max}$   $0.81 \times 10^4$ ,  $0.24 \times 10^4$  and  $0.82 \times 10^4$  L mol<sup>-1</sup> cm<sup>-1</sup> for  $I_a$ ,  $I_b$  and  $I_c$ , respectively. These bands are attributed to the transition within the quinoxaline moiety and the  $\pi$ - $\pi^*$  transition ( ${}^1L_b \leftarrow {}^1A$ ) for aromatic systems. Also, the first band has high extinction value and is solvent insensitive. The third band at 340, 330 and 317 nm with  $\epsilon_{\max}$   $0.64 \times 10^4$ ,  $0.12 \times 10^4$  and  $0.10 \times 10^4$  L mol<sup>-1</sup> cm<sup>-1</sup> for ligands  $I_a$ ,  $I_b$  and  $I_c$  respectively is very sensitive to solvent polarity. This band is probably of the charge transfer type. For all ligands  $I_{a-c}$  we observed a shoulder at 423, 390 and 364 nm for  $I_a$ ,  $I_b$  and  $I_c$  which can be explained the bases of an azo-hydrazo tautomeric equilibrium<sup>(3)</sup> of this compounds which can be represented as follows:

From Fig. (2) the CT band of compound  $I_c$  splits to two bands one of them at 293 nm and the other at 317 nm and this can be attributed to the intramolecular hydrogen bonds formed in this ligands which can be represented as follows:

The spectral data of these ligands are given in Table (2).

### 3.1.2. The electronic absorption spectra of Schiff bases in ethanol

The electronic absorption spectra of Schiff bases  $II_{a-c}$  under investigation in ethanol display bands as shown in Fig. (2).

The first band is observed at 230 and 225 (sh) nm with  $\epsilon_{\max}$   $0.2 \times 10^4$  and  $0.52 \times 10^4 \text{ L mol}^{-1} \text{ cm}^{-1}$  for  $II_a$  and  $II_b$  respectively, and this band due to transition ( ${}^1L_a \leftarrow {}^1A$ ) state in the phenyl ring for  $II_a$  and transition ( ${}^1B_a \leftarrow {}^1A$ ) state in naphthyl system for  $II_b$ . The second band observed at 277, 275 and 250 nm with  $\epsilon_{\max}$   $0.23 \times 10^4$ ,  $0.36 \times 10^4$  and  $0.71 \times 10^4 \text{ L mol}^{-1} \text{ cm}^{-1}$  for  $II_a$ ,  $II_b$  and  $II_c$ , respectively, may be due to  $\pi$ - $\pi^*$  transition of type ( ${}^1L_b \leftarrow {}^1A$ ) state occurring in the quinoxaline system. We found that this band is slightly influenced by organic solvents. The third band at 330, 330 and 311 nm with  $\epsilon_{\max}$   $0.18 \times 10^4$ ,  $0.30 \times 10^4$  and  $1.30 \times 10^4 \text{ L mol}^{-1} \text{ cm}^{-1}$  for  $II_a$ ,  $II_b$  and  $II_c$ , respectively, is due to the  $n$ - $\pi^*$  transition which occurs in the azomethine system. We observe from Fig. (2) that there is

a shoulder at 397, 415 and 425 nm for ligands II<sub>a</sub>, II<sub>b</sub> and II<sub>c</sub> respectively which may be due to the delodization of hydrogen atom from (OH) group to give keto form which can be represented as follows:

The spectral data of compounds II<sub>a-c</sub> are listed in Table (3).

### 3.2. The electronic absorption spectra of azo compounds under investigation in different organic solvents

The electronic absorption spectra of azo dyes I<sub>a-c</sub> were recorded in ethanol, acetonitril, dimethyl formamide (DMF), n-hexane, acetone and 1,4-dioxane as shown in Figs. (3-5). For the spectra of azo dyes ligands, its apparent that, the spectrum of each compound exhibits mainly two regions. The first region observed in the range 190-300 nm can be attributed to the localized transitions within phenyl and quinoxaline moieties. The second region appearing in range above 300 nm ascribed to CT transition within the molecule through azo group linkage. The first band which observed at 272 and 234 nm with  $\epsilon_{\max}$   $0.40 \times 10^4$  and  $1.14 \times 10^4$  L mol<sup>-1</sup> cm<sup>-1</sup> respectively for I<sub>b</sub> and I<sub>c</sub> is due to the  $\pi$ - $\pi^*$  transition which occurs within the quinoxaline system, other bands in the different organic solvents for the azo dye ligands are listed in Table (2). From the spectra of azo dye ligands (I<sub>a-c</sub>) it is apparent that, the spectrum of each compound exhibits mainly three bands. We observed that both intramolecular CT band and LE band are solvent sensitive but by different ways. For ligands I<sub>a</sub> and I<sub>b</sub> the polar solvent exhibits a band with

slight red shift which is referred to the  $\pi$ - $\pi^*$  transition occurring in azo groups (N=N). But for ligand I<sub>c</sub> there are no changes observed in the position of CT band for both polar on non polar solvents as shown in Fig. (5).

### 3.3. The electronic absorption spectra of Schiff base compounds under investigation in different organic solvents

It is apparent that the position and extinctions of bands appearing in the UV and visible regions are dependent on the polarity of the medium and the nature of substituents on the ligand molecules. The general trend observed shows that all  $\pi$ - $\pi^*$  transitions within the molecules are influenced by the n-electrons on the -N=CH- group and an intramolecular charge transfer. The visible band is slightly red shifted in ethanol than in n-hexane. This small red shift can be explained on the basis that the ethanol molecules may associate with (-OH) group through H-bond formation and this observed from the positions of absorption bands of Schiff base compounds after dissolving in different organic solvent as shown in Figs. (6-8).

For the spectra of Schiff base compounds, it is apparent that the spectrum of each compound exhibits mainly three bands as shown in Table (3), for DMF as organic solvent, the first band at 335 (sh) and 342 nm with  $\epsilon_{\text{max}}$   $0.28 \times 10^4$  and  $0.24 \times 10^4$  L mol<sup>-1</sup> cm<sup>-1</sup> for ligand II<sub>a</sub> and II<sub>b</sub> respectively, and this band due to the  $\pi$ - $\pi^*$  transition of phenyl ring, whereas the second band at 400, 413 and 311 nm with  $\epsilon_{\text{max}}$   $0.36 \times 10^4$ ,

$0.42 \times 10^4$  and  $1.11 \times 10^4 \text{ L mol}^{-1} \text{ cm}^{-1}$  is due to the electronic transition occurring within quinoxaline system. The third band which appeared at 436, 466 and 335 nm with  $\epsilon_{\text{max}}$   $0.48 \times 10^4$ ,  $0.44 \times 10^4$  and  $0.60 \times 10^4 \text{ L mol}^{-1} \text{ cm}^{-1}$  for ligands II<sub>a</sub>, II<sub>b</sub> and II<sub>c</sub> respectively is due to the CT transition which occurred through the azomethine group in Schiff base compounds. We observe that these bands appear at higher wavelength which may be due to intermolecular hydrogen bond between ligand and DMF.

In some case, although ethanol is a solvent with relatively high polarity compared to 1,4-dioxane and n-hexane, the UV band appearing in ethanol exhibits a slight blue shift compared to nonpolar solvents. This behavior may be attributed to the blocking of the n-electrons by ethanol molecules hence blocking the resonance on the aromatic ring. This renders the excitation of the  $\pi$ -electrons on the phenyl group more difficult, thus requiring higher energy, hence the small blue shift of such bands in ethanol<sup>(91)</sup>.

The shift in  $\lambda_{\text{max}}$  can be discussed in term of the solvent polarity viz dielectric constant and the possibility of formation of an intermolecular hydrogen bonds between ligand and solvent molecules.

The relation which governs this behavior was given by **Gati** and **Szalay**<sup>(92)</sup> in the form of:

$$\Delta\bar{\nu} = (a - b) \left( \frac{n^2 - 1}{2n^2 + 1} \right) + b \left( \frac{D - 1}{D + 1} \right)$$

In which a and b are constants depending on the nature of the solute, n is the refractive index and D is the dielectric constant of the medium.

According to this relation, the plot of  $\Delta\bar{\nu}$  as a function of the term would be a linear relation if the dielectric force is predominant. But the relation shows no straight lines indicating that the dielectric constant of the medium is not the main factor governing band shift. So, the main factors are the polarization forces and the solvent-solute interactions leading to intermolecular hydrogen bonding especially with protic solvents as well as changes in the solvation energy of both ground and excited states<sup>(93)</sup>.

For the spectra of Schiff base ligands ( $II_{a-c}$ ) it's apparent that, the spectrum of each component exhibits mainly two bands except in case of ligand  $II_c$  where only one band is observed in UV region with a shoulder at longer wavelength. We observe that both intramolecular CT band and LE band are solvent sensitive but in different ways. For ligands  $II_a$  and  $II_b$  the polar solvents have CT band with slight red shift compared with the nonpolar solvent and this CT band is referred to the  $\pi-\pi^*$  transition which occurs within the azomethine group.

Table (2): The spectral data of ligands  $I_{a-c}$  in different organic solvents

| Solvent     | $I_a$                   |                              |                         |                              |                         |                              |                         |

### **3.4. The spectral behavior of ligands under consideration in buffer solutions and the determination of their acid ionisation constants**

The acid ionization constants ( $pK_a$ ) of the ligands under investigation are determined spectrophotometrically in universal buffer solutions covering the pH range 2.04 to 12.04. The absorption spectra of both azo dyes and Schiff base compounds in buffer solutions of varying pH values are recorded within the wavelength range 250-600 nm. The bands of some compounds were shifted in their position or show variation in extinction whereas others exhibit a new band by increasing pH of the medium as shown in Figs. (9-14). The relation between pH and absorbance of each ligand are shown in Figs. (9-14) which give S-shape and the change of absorbance with pH can be utilized for determination of the dissociation constants by some methods. These include:

#### ***1- Half-height method<sup>(94)</sup>***

This method is based on the fact that at the half-height of the absorbance-pH curve, the dissociated and undissociated species exist in equivalent quantities, thus

$$pK = pH \quad \text{at } A_{1/2}$$

$$\text{where } A_{1/2} = [(A_{\max} - A_{\min}) / 2] + A_{\min}$$

#### ***2- The modified limiting absorbance method<sup>(95)</sup>***

This method has the advantage of eliminating any overlaps between absorbance of the two forms, and  $pK_a$  is calculated by equation

$$pH = pK + \log \gamma' + \log [(A - A_{\min}) / (A_{\max} - A)]$$

where

A = absorbance at a given pH value

$\gamma$  = the activity coefficient of the ion present at equilibrium

$A_{\min}$ ,  $A_{\max}$  are the absorbance corresponding to the total concentration of neutral and ionized species liable to exist in solution.

The  $pK_a$  value can be evaluated by plotting  $\log [(A-A_{\min})/(A_{\max}-A)]$  vs pH. The  $pK_a$  value thus corresponds to the pH value at zero  $\log [(A-A_{\min})/(A_{\max}-A)]$ .

### **3- The colleter method <sup>(96)</sup>**

This method is utilized in the form developed for the determination of the dissociation constants of weak acids. In this method, three absorbance values are taken at three different hydrogen ion concentration at the same wavelength.

The dissociation constants can be calculated using the following equations

$$K_a = \frac{C_{H_2^+} - MC_{H_3^+}}{M - 1}$$

in which

$$M = \left( \frac{A_3 - A_1}{A_2 - A_1} \right) \left( \frac{C_{H_1^+} - C_{H_2^+}}{C_{H_1^+} - C_{H_3^+}} \right)$$

Where  $A_1$ ,  $A_2$ ,  $A_3$  are the absorbance at three different  $H^+$  ion concentration  $C_{H_1^+}$ ,  $C_{H_2^+}$  and  $C_{H_3^+}$  respectively

The  $pK_a$  values determined by the different methods for the reagents  $I_{a-c}$  and  $II_{a-c}$  are given in Table (12).

### 3.4.1. The spectra of ligands I<sub>a</sub>, I<sub>b</sub>, and I<sub>c</sub> in universal buffer solutions

The spectra of  $1 \times 10^{-5}$  M of azo compounds I<sub>a</sub>, I<sub>b</sub> and I<sub>c</sub> in buffer solutions containing 30 % (v/v) ethanol of pH 2.04-12.04 are shown in Figs. (9-11).

The spectra of I<sub>a</sub> and I<sub>b</sub> show one band is  $\lambda_{\max}$  420 and 390 nm respectively which increased in extinction with increasing the pH of the medium. But in case of I<sub>c</sub>, the spectra show two bands of  $\lambda_{\max}$  388 and 483 nm where band at 388 nm increased in extinction with increasing the pH of the medium, but band at 483 nm decreased in extinction with increasing pH value. A clear isosbestic point for I<sub>c</sub> appeared at 455 nm, which indicates that an acid-base equilibrium occurred between the non-ionized and ionized species; this can be represented as follows:

The variation of absorbance with pH for I<sub>a</sub>, I<sub>b</sub> and I<sub>c</sub> at  $\lambda_{\max}$  gives S-shaped curves as shown in Figs (9-11) and data given in Tables (4-7).

### 3.4.2. The absorption spectra of ligands II<sub>a</sub>, II<sub>b</sub> and II<sub>c</sub> in universal buffer solutions

The absorption spectra of  $1 \times 10^{-5}$  M of Schiff-base compounds II<sub>a</sub>, II<sub>b</sub> and II<sub>c</sub> in buffer solutions containing 30% (v/v) ethanol are shown in Figs. (12-14). It is clear that the absorption of the species changes with increase of pH of medium.

In case of II<sub>a</sub> the spectra show one band at  $\lambda_{\text{max}} = 398$  nm with a shoulder at longer wavelength, which developed to a band at  $\lambda_{\text{max}} = 478$  nm with increasing pH values. In case of II<sub>b</sub> and II<sub>c</sub> only one band appears with  $\lambda_{\text{max}}$  of 410 and 394 nm respectively which increased in extinction with increasing the pH of the medium. A clear isosbestic point for II<sub>a</sub> appears at 425 nm, which indicates that an acid-base equilibrium occurred between the non-ionized and ionized species occurs in solutions; this may be represented as follows:

The variation of absorbance with pH of solution for compounds II<sub>a</sub>, II<sub>b</sub> and II<sub>c</sub> are given in Figs. (9-11) as S-shape with one or two inflection and data are given in Tables (4-7). The inflections lie within the pH ranges 3.2-6.4 and 7.1-10.5 revealing that the ionization of the two OH groups occurs in a stepwise manner.

Table (4). The colleter method of ligand  $I_a$  at  $\lambda_{max} = 420 \text{ nm}$

### 3.5. Infrared spectra of free azo dye and Schiff base compounds

This part includes an attempt to obtain the assignment for the important and characteristic bands in the IR-spectra of the reagent under investigation. The IR-spectra of the azo dye and Schiff base compounds under investigation are recorded in Figs. (15-17). The assignment of the important bands is given in Tables (52-57).

#### 3.5.1. Infrared spectra of azo dye compounds

In region of  $3500\text{--}3300\text{ cm}^{-1}$ , the bands due to the (OH) stretching vibrations are expected to appear. For the first series of compounds ( $I_{a-c}$ ), the  $\nu_{OH}$  band appears as a sharp absorption with medium intensity at frequency of  $3450$ ,  $3453$  and  $3413\text{ cm}^{-1}$  for  $I_a$ ,  $I_b$  and  $I_c$  respectively.

The  $\nu_{C-H}$  band for aromatic system appears at  $3010$ ,  $3022$  and  $3015\text{ cm}^{-1}$  for ligand  $I_a$ ,  $I_b$  and  $I_c$  respectively. The  $C=C$  band appears at  $1670$ ,  $1620$  and  $1510\text{ cm}^{-1}$  for  $I_a$ ,  $I_b$  and  $I_c$  respectively.

The spectra in range  $1600\text{--}1000\text{ cm}^{-1}$  of the azo dye compounds is of interest, since the bands observed are for  $\nu_{C=N}$ ,  $\nu_{N=N}$  and  $\nu_{C=O}$  vibrations. The IR spectra of compounds  $I_{a-c}$  show medium or weak intensity bands at  $1440$ ,  $1458$  and  $1465\text{ cm}^{-1}$  for ligand  $I_a$ ,  $I_b$  and  $I_c$  respectively due to the symmetric vibration of  $N=N$  group.

The  $\nu_{C=N}$  band is observed at  $1565$ ,  $1545$  and  $1505\text{ cm}^{-1}$  for ligand  $I_a$ ,  $I_b$  and  $I_c$  respectively. The appearance of the  $\nu_{C=N}$  band for these compounds gives an indication that azo  $\rightleftharpoons$  hydrazo equilibrium is liable to take place which can be represented as follows:

The position of  $\nu_{C=O}$  in this case appear at 1630, 1644 and 1620  $\text{cm}^{-1}$  for ligands  $I_a$ ,  $I_b$  and  $I_c$  respectively. In the spectra of range 1000-400  $\text{cm}^{-1}$ , most of strong bands appear in this region in the spectra of azo dyes under investigation which are attributed to the out of plane deformation vibration of the aromatic C-H bonds. The IR spectra of all compounds show a strong band in region 800-550  $\text{cm}^{-1}$  corresponding the out of plane of the aromatic hydrogen atom.

The bands around 1380-1330  $\text{cm}^{-1}$  are corresponding to the in-plane bending modes of OH group. Also, a band is observed around 1158-1220  $\text{cm}^{-1}$  corresponding to the stretching vibration of C-OH and that around 1500-1580  $\text{cm}^{-1}$  for stretching vibration of C=N bonds.

### **3.5.2. Infrared spectra of Schiff base compounds**

For ligands  $II_{a-c}$  and in region 3500-3300  $\text{cm}^{-1}$ , the bands due to the (OH) stretching vibration appeared at 3420, 3433 and 3490  $\text{cm}^{-1}$  for  $II_a$ ,  $II_b$  and  $II_c$  respectively. The in-plane bending modes of OH group appeared at 1345, 1343 and 1385  $\text{cm}^{-1}$  for ligand  $II_a$ ,  $II_b$  and  $II_c$  respectively. The  $\nu_{C=C}$  band appears at 1610, 1612 and 1615  $\text{cm}^{-1}$  for ligands  $II_a$ ,  $II_b$  and  $II_c$  respectively.

The aromatic C-H stretching vibrations bands occur in reagon 3080-3010  $\text{cm}^{-1}$  and are of strong to medium intentisty where its appear at 3065, 3050 and 3020  $\text{cm}^{-1}$  for ligand  $II_a$ ,  $II_b$  and  $II_c$  respectively.

The spectra in range 1700-1200  $\text{cm}^{-1}$  of Schiff base compounds show bands due to  $\nu_{C=O}$  and  $\nu_{sy C=N}$  where the symmetric vibrations of C=N group for Schiff base ligands at 1681, 1683 and 1690  $\text{cm}^{-1}$  for  $II_a$ ,  $II_b$  and  $II_c$  respectively and  $\nu_{C-OH}$  appeared at 1221, 1227 and 1161  $\text{cm}^{-1}$  for  $II_a$ ,  $II_b$  and  $II_c$  respectively.

### 3.6. $^1\text{H}$ -NMR spectra of ligands under consideration

A further support for the conclusion obtained from elemental analysis and IR spectra for the structure of ligands under investigation is gained by a consideration of their  $^1\text{H}$ -NMR spectra. The different types of hydrogen protons which are expected for the compounds under investigation can be formulated as follows:

### **3.6.1. $^1\text{H}$ -NMR spectra of azo dyes compounds ( $\text{I}_{\text{a-b}}$ )**

The different types of signals for the hydrogens which are expected for the azo dyes compounds are shown in Fig. (18) and the chemical shift of different types of protons are recorded in Table (13). Also, the hydrogen magnetic resonance spectra of  $\text{I}_{\text{a}}$  and  $\text{I}_{\text{b}}$  on deuteration with  $\text{D}_2\text{O}$  are shown in Fig. (18). All signals observed take the integration value which give evidence and helps to assign the signals. The signals lying at very downfield side 13.2 and 10.0 ppm respectively for  $\text{I}_{\text{a}}$  and  $\text{I}_{\text{b}}$  are removed after deuteration which give evidence that they are due to the hydrogens of OH groups which are attached either to quinoxaline system or naphthalene system. On going from ligand  $\text{I}_{\text{a}}$  or  $\text{I}_{\text{b}}$  a new multiple signals at ranges 6.60-8.23 and 6.50-7.80 ppm, respectively which is due to the protons of the phenyl group didn't disappear after deuteration.

### **3.6.2. $^1\text{H}$ -NMR spectra of Schiff base compounds ( $\text{II}_{\text{a-c}}$ )**

The  $^1\text{H}$ -NMR spectra of  $\text{II}_{\text{a-c}}$  as well as its deuteration by  $\text{D}_2\text{O}$  are shown in Figs. (18, 19) and chemical shift of the different signals are recorded in Table (13).

Also, it is clear from the  $^1\text{H}$ -NMR spectra of  $\text{II}_{\text{a}}$ ,  $\text{II}_{\text{b}}$  and  $\text{II}_{\text{c}}$  that the signals lying at very downfield side 10.24, 10.43 and 11.21 ppm respectively, which are removed on deuteration give evidence that they are due to the hydrogens of OH group which attached to the quinoxaline system, while the signals at 8.9, 9.6 and 12.04 ppm are due to the OH group which is attached to the phenyl ring in case of  $\text{II}_{\text{a}}$ , and  $\text{II}_{\text{c}}$  and to the naphthalene system in case of  $\text{II}_{\text{b}}$ .

Also, in ligand  $\text{II}_{\text{c}}$  the signal of OH group at 12.04 ppm was downfield side compared with the other two Schiff base ligands which is

due to the presence of the bromide atom in para position which can withdraw the electron cloud from the aromatic ring this affect the OH group.

The signals observed at 6.7, 6.56 and 6.64 ppm were due to the azomethene group of ligands II<sub>a</sub>, II<sub>b</sub> and II<sub>c</sub> respectively.

**Table (13): Assignment and chemical shift (ppm) of different types of protons of ligands under investigation.**

| Compound        | Chemical shift ( $\delta$ ) (ppm) of protons |                     |                      |                     |                     |                     |
|-----------------|--|---------------------|----------------------|---------------------|---------------------|---------------------|
|                 | H (1) <sub>OH</sub>                          | H (2) <sub>OH</sub> | H (3) <sub>-CH</sub> | H (4)               | H (5)               | H (6)               |
| I <sub>a</sub>  | 10.12,<br>10.23                              | 13.20               | -                    | 6.60, 6.69,<br>6.64 | 8.06, 8.19,<br>8.23 | 7.70, 7.43,<br>7.63 |

### 3.7. Cyclic voltammetry of free ligands

The electrochemical behavior of ligands,  $I_a$ ,  $I_c$ ,  $II_a$  and  $II_b$  was studied by cyclic voltammetry in 30 % ethanol using B-R buffer solutions in the pH range 2.3 - 11.3.

#### 3.7.1. Cyclic voltammetric behavior of ligands $I_a$ and $I_c$

Typical cyclic voltammograms obtained for  $1 \times 10^{-4}$  M solutions of ligands  $I_a$  and  $I_c$  are shown in Figs. (20-22) respectively. One well-defined reduction peak was obtained at about -630 mV for  $I_a$  and at about -50 mV for  $I_c$  along the entire pH range. In the reverse direction, one anodic peak was observed at about +400 mV for  $I_c$ . The height of the oxidation peak is about half the height of the reduction wave in case of  $I_a$  and about the same height in case of  $I_c$ .

The dependence of cathodic peak currents ( $I_{pc}$ ) and anodic peak currents ( $I_{pa}$ ) on the pH are shown in Figs. (21, 23).

The effect of scan rate ( $\nu$ ) on the cyclic voltammetric parameters was investigated for  $I_a$  and  $I_c$  at pH 6.70 and 6.05, respectively. The reduction peak current  $I_{pc}$  is a linear function of  $\nu^{1/2}$  for the two ligands under consideration, indicating that the reduction process is controlled mainly by diffusion. The shift of  $E_p$  to more negative potentials is an evidence for the irreversible nature of the electrode reaction.

The ratio of the anodic-to-cathodic peak heights ( $I_{pa}/I_{pc}$ ) for the two ligands remains unchanged with the change of scan rate ( $\nu$ ). The reduction potentials for the reduction peak shifts to more negative values, while the oxidation potential for the oxidation peak shifts to more positive values on increasing  $\nu$ , for the both ligands under investigation.

The influence of pH on the peak potential ( $E_p$ ) and peak current ( $I_p$ ) was investigated at  $\nu = 200, 500 \text{ mVs}^{-1}$  for  $I_a$  and  $I_c$ , respectively. The

potential of the cathodic peak ( $I_{pc}$ ) shifts towards more negative values as pH increases for the two ligands examined, resulting in a linear plot of mV per pH unit with slope equal to  $\alpha n$  where  $\alpha$  is the charge transfer rate constant and  $n$  the number of electrons involved in electron transfer processes. This indicates that hydrogen ions are involved in the electrode reaction<sup>(97)</sup>.

From polarographic and voltammetric measurements of several azo compounds, it is known that the reduction of aromatic azo compounds containing electron donating substituents, such as hydroxyl groups, involve a cleavage of the azo bridge to yield the corresponding amines in acidic solutions. On increasing the pH, the reduction of the azo compound stops at the hydrazo step. The cleavage of the azo bridge should be a four electron process, while a saturation to hydrazo involves only two electrons<sup>(98, 99)</sup>.

According to the data obtained from cyclic voltammetry, the reduction mechanism can be suggested as:

### 3.7.2. Cyclic voltammetric behavior of ligands II<sub>a</sub> and II<sub>b</sub>

The cyclic voltammograms of  $1 \times 10^{-4}$  M ligands II<sub>a</sub> and II<sub>b</sub> were recorded in B-R buffer over the pH range 2.5-11.3, Figs. (24, 26). For the two compounds, cyclic voltammograms at  $200 \text{ mVs}^{-1}$  consist of a single cathodic wave at potentials at about -800 and -750 mV for II<sub>a</sub> and II<sub>b</sub>, respectively. No anodic wave occurs in the reverse scan direction. This behavior was observed for a wide range of scan rates from 50 to 1000  $\text{mVs}^{-1}$ . Hence, such a reduction process should correspond to a totally irreversible electron transfer. The dependence of the cathodic peak currents on pH of the two ligands are shown in Figs. (25, 27).

The plot  $I_{pc}$  vs.  $v^{1/2}$  showed a linear variation due to a diffusion-controlled mechanism. On the other hand,  $E_{pc}$  was independent of  $\log v$  between 50-1000  $\text{mVs}^{-1}$ .

The cathodic peak is due to the reduction of the imine bond,  $\text{C}=\text{N}$  of the ligands II<sub>a</sub> and II<sub>b</sub>. The reduction mechanism for the two ligands can be suggested as:

The effect of scan rate on cyclic voltammogram recorded on ligand (I<sub>a</sub>) in 30% ethanol using a glassy carbon electrode
