# ***Analysis of the Results***

The study included 50 preterm newborns consequently admitted to El-Mansoura general hospital and (NICU) of Mansoura University Children Hospital (MUCH) the period from March 2009 till December 2009.

## **All neonates were subjected to :**

### ***A. Complete history taking including:***

1. Antenatal history of maternal diseases, maternal fever, maternal use of antenatal steroids with its type, dose and time of administration, ..etc.
2. Natal history of mode of delivery, premature rupture of membranes,..etc.

### ***B. Complete clinical examination to assess:***

\_gestational age by Ballard score, Apgar scores at 1&5 minutes, degree of respiratory distress syndrome using Downes score.

### ***C. Chest X. ray .***

### ***D. Laboratory investigations included:***

1. Arterial blood gases (ABG).
2. Cord blood VEGF level using (ELISA) method .

All babies were followed in the neonatal intensive care unit ( *NICU* ) for possibility of developing RDS .

Babies who did not develop respiratory distress syndrome (RDS) were classified into group I ( *control group* ) , they were 10 preterm infants.

While babies who developed RDS were classified into group II ( 40 preterm infants) .

The descriptive data in **Table(9)** shows that :

Male preterm infants represent 60% of the preterm infants with RDS cases, whereas half the number of preterm infants without RDS were males.

Higher incidence of preterm infants who did not develop RDS (70%) were born vaginally, whereas the incidence of cesarean section is high in those developing RDS (65%) .

PROM occurred in almost 40% of preterm infants in both groups.

Antenatal steroids were given in 80% of the preterm infants who didn't develop RDS, and in 60% of preterm infants who developed RDS.

65% of the preterm infants with RDS were given rescue surfactant after delivery.

CPAP was used in almost 28% of preterm infants who developed RDS, while assisted ventilation was used in 40% of the same group.

None of the preterm infants who did not develop RDS died , while death occurred in 20% in the preterm infants with RDS.

The mean gestational age in weeks ( $34.9 \pm 1.1005$ ) for preterm infants without RDS & the mean gestational age in weeks ( $32.975 \pm 2.7408$ ) for preterm infants with RDS with high statistically significant difference between the two groups ( $P < 0.05$ ), as shown in table No.10 and figure No.20.

The birth weight in kg ( $1.95 \pm 0.31$ ) for preterm infants without RDS & the mean birth weight in kg ( $1.675 \pm 0.461$ ) for preterm infants with RDS with statistically significant difference between the weight of the two groups ( $P < 0.05$ ), as shown in table No.11 and figure No.21.

No significant difference in concentrations of VEGF between male and female infants in both studied groups ( $p > 0.05$ ) as shown in table No.12. and figure No.22.

No significant difference in concentrations of VEGF between infants whose mothers had PROM or not in both studied groups ( $p > 0.05$ ) as shown in table No.14. and figure No.24.

No significant difference in concentrations of VEGF between infants whose mothers received antenatal steroids or not in both studied groups ( $p > 0.05$ ) as shown in table No.15. and figure No.25.

No significant correlations between VEGF levels and gestational age for both studied groups ( $p > 0.05$ ) as shown in table No.16. and figure No.26.

No significant correlations between VEGF levels and birth weight for all studied groups ( $p > 0.05$ ) as shown in table No.17. and figure No.27.

Highly significant difference found in the concentrations of VEGF between the preterm infants without RDS 227.5(75-830) pg/ml & the preterm infants with RDS 24.9(15-78.3) pg/ml ( $p < 0.001$ ), as shown in table No.18. and figure No.28.

Highly significant difference found in the concentrations of VEGF between the preterm infants with mild RDS 74.4(73.5-78.3) pg/ml , the preterm infants with moderate RDS 74.6(41-78.3) pg/ml & the preterm infants with severe RDS 22.1(15-33) pg/ml ( $p < 0.001$ ), as shown in table No.19. and figure No. 29.

**Table (9)** represent clinical data measured and reported at time of delivery as gestational age, birth weight, apgar score at 1 min, apgar score at 5 min, ABG score, Downes score and X-ray score (reported at admission) .

High significant correlations between VEGF levels and various variables (apgar score at 1 min , apgar score at 5 min , Downes score , ABG score, X-ray score) for preterm infants with RDS ( $p < 0.001$ ) as shown in tables No.20, and figures no.30,31,32,33,34.

There was a significant positive correlation between VEGF level and Apgar score at 1 min & 5 min ( $p < 0.001$ ) among preterm infants with RDS as shown in table No.20 and figures No.30,32.

There was a significant negative correlation between VEGF level and Downes score, ABG score & X-ray score ( $p < 0.001$ ) among preterm infants with RDS as shown in table No.20 and figure No.32,33,34.

Highly significant difference was found in the concentrations of VEGF between the preterm infants who didn't need respiratory support 74.4(73.5-78.3) pg/ml and preterm infants who needed respiratory support ( either CPAP or M.V ) 24.4(15-78.3) pg/ml ( $p < 0.001$ ), as shown in table No.22. and figure No. 36.

Highly significant difference was found in the concentrations of VEGF in the group of preterm infants who developed RDS between infants given rescue surfactant 22.5(15-33) pg/ml and infants not given surfactant 74(15-78.3) pg/ml ( $p < 0.001$ ), as shown in table No.21. and figure No. 35.

Significantly lower concentrations of VEGF found in preterm infants developing RDS with higher incidence of endotracheal tube intubation 22.1 (15-33) pg/ml compared with other preterm infants from the same group 74.5(41-78.3) pg/ml , ( $p < 0.001$ ) as shown in table No.23 and figure No.37.

The preterm infants with RDS who died had significantly lower VEGF concentrations than the preterm infants with RDS who survived [ 37 (17-78.3) v 19 (15-25) ] pg/ml , ( $p < 0.001$ ) as shown in table No.24 and figure No.38.

Cord blood VEGF elevation was significantly correlated with an absence of RDS as the specificity of cord blood VEGF above 30.5 pg/ml for predicting the absence of RDS was 80%, the sensitivity was 57.5% with area under curve 0.888 and significance of 0.0001 as shown table No.25 and figure No.39.
