# **Role of mri in evaluation of failed backsurgery syndrome of lumbar spine**

**Fakhry Mahmoud Hussein Oboda**

Female breast cancer seems to be responsible for the highest proportion of all female cancer deaths. It is the most common female malignancy of midlife accounting for 31.3% of all cancers among Egyptian women in Cairo metropolitan area. In recent years, our knowledge of breast cancer has progressed rapidly resulting in new approaches and techniques. The goal of the clinician is to differentiate between benign and malignant masses. Still nowadays the commonest investigation is mammography. In the management of breast cancer, the contralateral breast should be examined by mammography, because about 3% of patients will have contralateral mammography detectable but clinically occult cancer. Also breast cancer now is considered a systemic disease. Due to difficulties in interpretation of mammogram as in delineation of the lesion margin or the size of the tumor when arising in dense breast (specially the women age from 25-35 years) with hazards of ionizing radiation to these categories of young female. So additional modality as ultrasonography .
